Regression with Panel Data

SW Chapter 10

Types of data

Difference-in-differences

Two-period panel data analysis

Fixed effects

Least squares assumptions

- Understand difference between types of data
- ► Conduct difference-in-difference regressions
- Estimate first-difference regressions with panel models
- Estimate and interpret regressions with entity-level fixed effects, time-level fixed effects, and with both entity and time fixed effects
- Understand challenges to valid estimation under fixed effect models
- Use clustered standard errors to account for autocorrelation within panel data

Types of data

- Cross-sectional: random (independent) sampling of units at one point in time
 - ► What we've been using so far!
 - Relationship between hours worked and wages
 - ► How CEO tenure relates to compensation
- ► Time-series: observations over time
 - Stock-market dividends for Apple over the past 10 years
 - ► GDP growth over time
 - Annual infant mortality rates

▶ Panel (longitudinal): Cross-sections over time

- ► Track how individuals' earnings change over time
- Crime rates by city over time
- Very useful for policy analysis!
- Different from a "pooled cross-section" (multiple cross sections) like lots of waves of the ACS – different units each time

Cross-sectional data

Panel vs. repeated cross-sections

► Repeated (or pooled) cross-sections:

- Draw randomly from large population at various points in time
- Observations are independent over time: Bob surveyed in 1990 is independent of Jane in 1991
- Independence \Rightarrow inference is pretty easy!
- Panel data
 - Track the same population at various points in time
 - Population may be independent at first draw: Bob in 1990 is independent of Jane in 1990
 - ▶ But dependence over time: Bob in 1990 is related to Bob in 1991
 - Dependence \Rightarrow Detroit will probably have high crime rates next year.

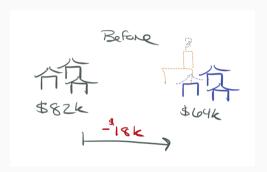

Difference-in-differences

Consider effect of the location of a house on its price before and after the garbage incinerator was built:

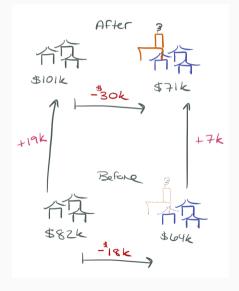

No! Look at the relationship between pricing and incinerator location *before* incinerator was built

Before incinerator was built:

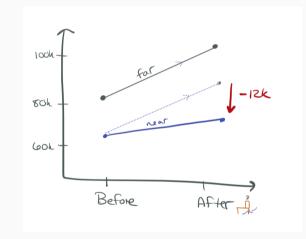

We should account for this:

$$\hat{\delta_1} = -30688.27 - (-18824.37) = -11863.90$$

- ► Incinerator reduces prices by \$12k
- ► This is equivalent to the following:

$$\hat{\delta}_1 = (rpri\bar{c}e_{1,nr} - rpri\bar{c}e_{1,fr}) - (rpri\bar{c}e_{0,nr} - rpri\bar{c}e_{0,fr})$$

We can capture this in a single regression:

 $rprice = \beta_0 + \delta_0 after + \beta_1 nearinc + \delta_1 after X nearinc + u$

- Easy to estimate both coefficients and standard errors
- If houses sold before and after incinerator was built were systematically different, want to control for those differences
- Doing this will reduce error variance and standard errors

We can apply this logic to evaluate the impact of policies for which we have a before and after period, and groups that were and were not affected:

$$y = \beta_0 + \delta_0 after + \beta_1 treated + \delta_1 after X treated + other + u$$
$$\hat{\delta_1} = (\bar{y}_{1,T} - \bar{y}_{1,C}) - (\bar{y}_{0,T} - \bar{y}_{0,C})$$

	Before	After	After - Before
Control	β_0	$\beta_0 + \delta_0$	δ_0
Treatment	$\beta_0 + \beta_1$	$\beta_0 + \delta_0 + \beta_1 + \delta_1$	$\delta_0 + \delta_1$
Treatment - Control	β_1	$\beta_1 + \delta_1$	δ_1

Two-period panel data analysis

- Now, assume we have the same observations over two time periods
- Consider relationship between unemployment rates and crime
 - Detroit has high unemployment rates and high crime
 - Does high unemployment cause high crime, or is there another explanation?
 - Explanatory variables could help

Effect of unemployment on city-level crime rates

- Assume that no other explanatory variables are available. Will it be possible to estimate the causal effect of unemployment on crime?
- Yes, if cities are observed for at least two periods and other factors affecting crime stay approximately constant over those periods.
- Consider a set of cities observed in two periods 1982 and 1987:

$$crimerte_{it} = \beta_0 + \delta_0 d87_{it} + \beta_1 unemp_{it} + a_i + u_{it}$$
$$t = 1982, 1987$$

- ► *d*87_{*it*}: time dummy for second period
- ► *a_i*: unobserved time-constant factors (fixed effects)
- $u_{i,t}$: other unobserved factors (idiosyncratic error)

 $\Delta crmrte_i = \delta_0 + \beta_1 Deltaunemp_i + \delta u_i$

See how the fixed effect drops out!

You can estimate a first-differenced equation using OLS

$\Delta \widehat{crmrte} = 15.4 + 2.22 \Delta unemp$

A 1pp increase in unemployment rate \Rightarrow 2.22 more times per 1,000 people

- The first-differenced panel estimator lets us causal effects in the presence of time-invariant endogeneity
- ► Will not solve time-variant endogeneity!
- However, first-differenced estimates will be imprecise if explanatory variables vary only little over time (no estimate possible if time-invariant)

Fixed effects

- What if, instead of differencing out individual-level characteristics? What if we control for them?
- For example, if we look at a panel of wages over time, there might be omitted Bob-specific characteristics:
 - ▶ Bob is hard working (+),
 - ► Bob is a competitive negotiator (+)
 - Bob smells funny (-)
 - ► We can never control for all of them.

- ▶ We can never control for all of Bob's unique quirks and features.
- ▶ But, we can "control for" Bob.
- We will give Bob his very own fixed effect: the unique "stuff" that Bob brings to the table.
- Only covers stuff that stays constant over time.

$$y_{it} = \beta_1 x_{it1} + \dots + \beta_k x_{itk} + a_i + u_{it}$$
$$\bar{y}_{it} = \beta_1 \bar{x}_{it} + \dots + \beta_k \bar{x}_{ik} + \bar{a}_i + \bar{u}_i$$
$$[y_{it} - \bar{y}_i] = \beta_1 [x_{it1} - \bar{x}_{i1}] + \dots + \beta_k [x_{itk} - \bar{x}_{ik}] + [u_{it} - \bar{u}_i]$$

Because $a_i - \bar{a}_i = 0$, the fixed effect drops out

- Estimate time-demeaned equations by OLS
- ▶ Uses time variation within cross-sectional units: within estimation
- Functionally equivalent to including a dummy variable for ever *i* (fixed effect)

1. Hard way:

- Demean your data by hand
- Estimate OLS on demeaned data
- 2. Easier way:
 - Estimate OLS, including fixed effects by using dummy variables
 - ► The command **areg** will let you absorb, or "eat up," one set of fixed effects
- 3. Powerful way:
 - ► Tell Stata you have panel data using xtset
 - Estimate using xtreg (still OLS)

Least squares assumptions

Least squares assumptions for panel data

Consider a single X:

$$Y_t = \beta_1 X_{it} + \alpha_i + u_{it}, i = 1, ..., n; t = 1, ...T$$

1. $E[u_{it}|X_{i1},...X_{iT},\alpha_i) = 0$

2. $(X_{i1}, ..., X_T, u_{i1}, ..., u_{iT}), i = 1, ..., n$ are i.i.d. draws from their joint distribution

- 3. (X_{it}, u_{it}) have finite fourth moments
- 4. No perfect multicollinearity
- ► *u_{it}* cannot be correlated with any **present**, **past**, **or future** values of *X*!
- However, only have to be independent draws across entities

If these hold, estimates are consistent and normally distributed for large *n*!

 $Y_{it} = \alpha_i + \beta_1 X_{it} + \omega_{it}$

- Time-varying omitted variable is ω_{it}
- $\blacktriangleright \omega_{it}$ reflects factors changing over time that affect outcome
- ▶ If Y_{it} is traffic fatalities, maybe ω_{it} includes road repairs in state *i*
- Likely quality of roads last period in state *i* are similar to quality of roads in this period
- Roads yesterday are about the same as roads today

- Previously, we assumed that different observations were independent
 - ▶ No twins, no school districts in the same county
- ► Implausible for state data over time
- ► Data on the same entity over time is likely to suffer from autocorrelation
- Without correction, we will estimate incorrect standard errors, inference will be wrong

- Clustered standard errors correct for autocorrelation
- Otherwise, confidence intervals will not have 95
- ► Suppose entity is a U.S. state
 - ► Tell Stata to allow for omitted variables ω_{it} for different time periods from same state to be correlated
 - Add option cluster(state) to regress or add option vce(cluster) to xtreg

- Covariates: The fixed effect covers all time-invariant factors! (So you don't need them in your model)
- Interpreting fixed effects models:
 - We don't usually look at the coefficients on the fixed effects themselves, though they can be informative.
 - Which fixed effect is "omitted" avoiding the dummy variable trap doesn't really matter, because we're not interpreting them!
 - Not reported in regression estimates
- Changes interpretation of models
 - Only look at effect of variables that change over time

Summary

Difference-in-differences specifications

- Repeated cross-sectional data at two points in time
- ▶ Often a "before" vs. "after" and a "treatment" vs. "control"
- ▶ GM assumptions apply for OLS to be BLUE
- Assumptions we need:
 - Parallel trends assumption: That in absence of "treatment," gap between two groups would have stayed parallel
- Assumptions we don't need:
 - There can be unobserved factors that happened at one point of time, if they affect the two groups equally
 - The two groups can be very different from each other, so long as they are on the same trajectories

First-difference models

- ▶ Panel data
- Regress the change in Y on change in X
- Assumptions we need:
 - Still have to be careful of any omitted characteristics that vary over time
- Assumptions we don't need:
 - ► Any time-invariant characteristics are differenced out! ⇒ no time-invariant omitted variable bias!

Interesting ways to work with panel data

Fixed effects

- ▶ Panel data
- ► Regress Y on X , include entity-specific and/or time-specific fixed effects

Assumptions we need:

- With entity-effects only: Still have to be careful of any omitted characteristics that vary over time
- With time-effects only: Still have to be careful of any omitted characteristics that vary across entities at a particular period in time
- ▶ With both: Careful of omitted characteristics that vary across entities and time

Assumptions we don't need:

- ► Any time-invariant characteristics are controlled! ⇒ no time-invariant omitted variable bias!
- ► Any entity-invariant characteristics are controlled! ⇒ no omitted variable bias for aggregate time shocks!
